Syntactic sugar

For comprehensions

Syntactic sugar

- **For comprehensions**
- By-name parameters
- Non local return
- String interpolation

Questions?

"For comprehensions" is syntactic sugar:

```
//map
for (i <- 1 to 5) yield i * i
//foreach
for (i <- 1 to 5) println(i)
//flatMap
for {
  i <- 1 to 5
  j <- 1 to
} yield i + j
```

```
//map
(1 to 5).map { i => i * i }
//foreach
(1 to 5).foreach { i =>
  println(i)
}
//flatMap
(1 to 5).flatMap { i =>
  (1 to 5).map { j => i + j }
}
```

For comprehensions

Syntactic sugar

● For comprehensions

- By-name parameters
- Non local return
- String interpolation

Binary compatibility

Questions?

Irrefutable pattern means that matching can be checked by compiler, otherwise additional 'withFilter' will be generated:

```
val matrix: Seq[Seq[Int]] = ???  
for (Seq(x, y) <- matrix)  
  yield x + y
```

```
val matrix: Seq[Seq[Int]] = ???  
matrix.withFilter {  
  case Seq(x, y) => true  
  case _ => false  
} map {  
  case Seq(x, y) => x + y  
}
```

By-name parameters

Syntactic sugar

- For comprehensions
- **By-name parameters**
- Non local return
- String interpolation

Generated ByteCode

Binary compatibility

Questions?

By-name parameters is just shorthand:

```
def foo(x: => Int) {  
  println(x)  
}  
  
foo(1)
```

```
def foo(x: () => Int) {  
  println(x())  
}  
  
foo(() => 1)
```

So evaluation of call-side code is made on every parameter usage.

Non local return

Syntactic sugar

- For comprehensions
- By-name parameters
- **Non local return**
- String interpolation

Generated ByteCode

Binary compatibility

Questions?

Return statement inside of closure throws `NonLocalReturnControl`.

- It consumes additional CPU
- Don't catch this Throwable
- Don't miss that return is non-local inside of "for statement"

String interpolation

Syntactic sugar

- For comprehensions
- By-name parameters
- Non local return
- **String interpolation**

Questions?

New Scala 2.10 syntactic sugar example

```
val link = 1  
ref"Obviously ${link} = 1"
```

```
val link = 1  
StringContext("Obviously ",  
              " = 1").ref(link)
```

Note: this is backward incompatible Scala syntax change

Local functions

Syntactic sugar

Generated ByteCode

● Local functions

- Classes and names
- Objects
- Traits
- Trait subclasses
- Linearization
- Initialization order

Binary compatibility

Questions?

Let's look how it compiles

```
class LocalFunctions {  
  def foo {  
    var i = 1  
    val j = 2  
    def local {  
      i += j  
    }  
    local  
    local  
  }  
}
```

```
import scala.runtime.IntRef;  
public class LocalFunctions {  
  public void foo() {  
    IntRef i$1 = new IntRef(1);  
    int j$1 = 2;  
    local$1(i$1, j$1);  
    local$1(i$1, j$1);  
  }  
  private final void local$1(  
    IntRef intref, int i) {  
    intref.elem += i;  
  }  
  public LocalFunctions() {}  
}
```

We can see that it's very similar to Java private members usage

Lazy values

- Trait subclasses
- Linearization
- Initialization order

Binary compatibility

Questions?

This is also some shorthand for some usual Java usages

```
class Lazy {  
  lazy val x = 1  
}
```

```
import scala.runtime.BoxedUnit;  
public class Lazy {  
  public int x() {  
    if ((bitmap$0 & 2) == 0)  
      synchronized (this) {  
        if ((bitmap$0 & 2) == 0) {  
          x = 1;  
          bitmap$0 = bitmap$0 | 2;  
        }  
        BoxedUnit _tmp =  
          BoxedUnit.UNIT;  
      }  
    return x;  
  }  
  public Lazy() {}  
  private int x;  
  public volatile int bitmap$0;  
}
```

Lazy vals can produce deadlocks

Questions?

All Unicode symbols have equivalent

- `:` \rightarrow `$colon`
- `+` \rightarrow `$plus`
- `©` \rightarrow `$u00A9`

In Scala code you can use both identifier variants.
Try `NameTransformer.encode/decode` from
`scala-compiler.jar`.

Objects

Syntactic sugar

Generated ByteCode

- Local functions
- Lazy values
- Classes and names
- **Objects**
- Traits
- Trait subclasses
- Linearization
- Initialization order

Binary compatibility

Questions?

Object is actually two classes in bytecode

- Object\$ contains static field MODULE\$, and compiled code of all members
- Object contains all static members of object with body Object\$.MODULE\$.foo()

Objects

Syntactic sugar

Generated ByteCode

- Local functions
- Lazy values
- Classes and names
- **Objects**
- Traits
- Trait subclasses
- Linearization
- Initialization order

Binary compatibility

Questions?

Static members added for compatibility with Java, however sometimes static members are not generated in

- Companion Trait
- Companion Class if it contains member with the same name
- Members of `java.lang.Object`

Traits

Syntactic sugar

Generated ByteCode

- Local functions
- Lazy values
- Classes and names
- Objects
- **Traits**
- Trait subclasses
- Linearization
- Initialization order

Binary compatibility

Questions?

For every trait will be generated Trait\$class with members implementation

```
trait A {  
  val x = 1  
  
  def foo(x: Int) = 2  
}
```

```
public abstract class A$class {  
  public static int foo(A $this,  
                        int x) {  
    return 2;  
  }  
  public static void $init$(  
    A $this  
  ) {  
    $this.  
      test$A$_setter_$x$_eq(1);  
  }  
}
```

Trait subclasses

Syntactic sugar

Generated ByteCode

- Local functions
- Lazy values
- Classes and names
- Objects
- Traits
- **Trait subclasses**
- Linearization
- Initialization order

Binary compatibility

Questions?

Java class implementing trait can simply implement implemented trait members in the following way

```
int foo() { return Trait$class.foo(this); }
```

In Scala compiler does the same automatically

Linearization

Syntactic sugar

Generated ByteCode

- Local functions
- Lazy values
- Classes and names
- Objects
- Traits
- Trait subclasses
- **Linearization**
- Initialization order

Binary compatibility

Questions?

Compiler needs this algorithm to define search order for members from base classes

```
trait A extends B
trait B
class C extends B
class D extends C with A
```

Linearization

Syntactic sugar

Generated ByteCode

- Local functions
- Lazy values

Binary compatibility

Questions?

Compiler needs this algorithm to define search order for members from base classes

```
trait A extends B
trait B
class C extends B
class D extends C with A
```

Linearization is D, A, C, B.

Linearization

Syntactic sugar

Generated ByteCode

- Local functions
- Lazy values
- Classes and names
- Objects
- Traits
- Trait subclasses
- **Linearization**
- Initialization order

Binary compatibility

Questions?

If two members with the same signature inherited by some class and one of members has modifier 'override' then overriding can happen implicitly according to linearization rules.

Initialization order

Syntactic sugar

Generated ByteCode

- Local functions
- Lazy values
- Classes and names
- Objects
- Traits
- Trait subclasses
- Linearization
- **Initialization order**

Binary compatibility

Questions?

Initialization order is opposite to linearization order. If you try to use `val` before its initialization, you can get NPE.

There are two ways to avoid possible NPE:

- Use lazy `val`
- Use early definitions

Methods

Syntactic sugar

Generated ByteCode

Binary compatibility

● **Methods**

● Values

● Lazy values

Questions?

This is similar to Java

- You can add methods to trait, but only if old members haven't link to new methods, because implementation will not be added to inheritors.
- Do not add methods to Companion Object with name, which Class contains, because static implementations will be removed by compiler.

Values

Syntactic sugar

Generated ByteCode

Binary compatibility

- Methods
- **Values**
- Lazy values

Questions?

Value in class and object compiled to getter (setter?) and field, which is initialized in constructor. So it's like with methods.

Trait value compiled in the same way. Just field initialization in method `Trait$class.$init$`.

- Don't add values to traits
- Don't change `def` to `val`
- Don't change `val` to `def`, because field won't be initialized

Lazy values

Syntactic sugar

Generated ByteCode

Binary compatibility

- Methods
- Values
- **Lazy values**

Questions?

Field bitmap is not generated if base class contains such field

- In such cases do not add lazy values to classes
- You can add lazy val to Trait, but this value shouldn't be used in old code
- You can change lazy val to def and vice versa, however inheritors won't see such changes
